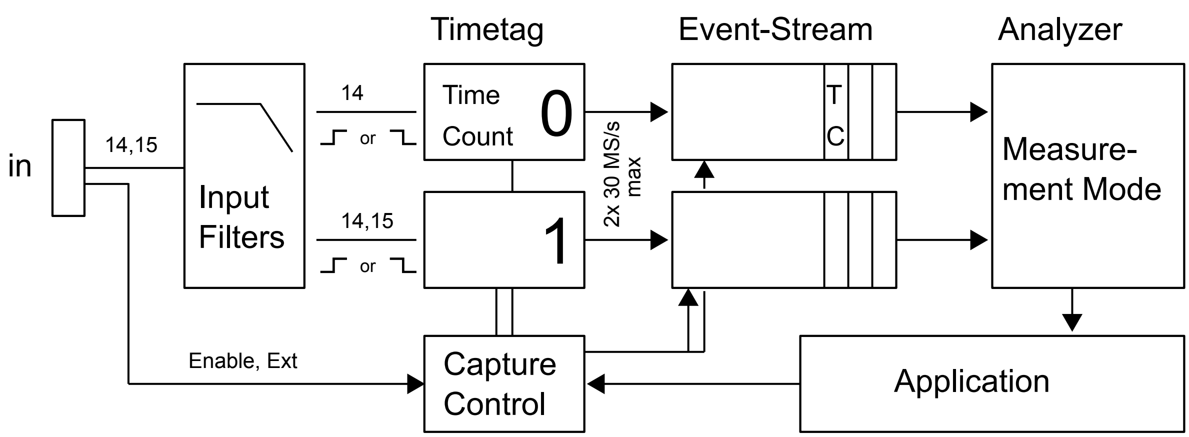
1 Overview

Figure 1: Timing Analyzer Architecture



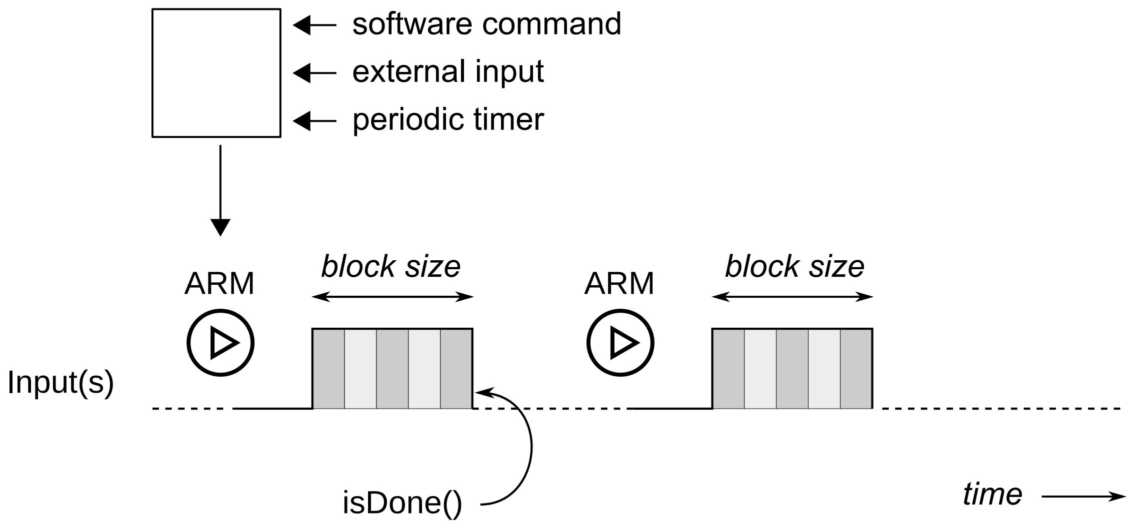
The TIC-8420 system is shown in Figure 1. After optionally low-pass filtering the inputs, the Timetag unit continously counts edges and records the time of their appearance. At the same time, the Capture Control unit decides when to capture a count-time pair (event) into the Event-Stream.

The Analyzer functions consume the events from the Event-Stream in order to provide measurement results to the application program.

Due to the continous event streaming architecture all measurements can be made on a zero-dead-time basis (back to back) without loss of data. Within the limits of bus speed (USB/PCI) events may be logged continously.

An IMPORTANT NOTICE at the end of this document addresses availability, warranty, changes, use in safety-critical applications, intellectual property matters and other important disclaimers.

Figure 2: Arming for Measurements



In any mode, the acquisition of timing data begins with the ARM signal. The ARM signal can be given "on-demand" by software control, external pulse, or on periodic timer intervals (Figure 2).

Block size

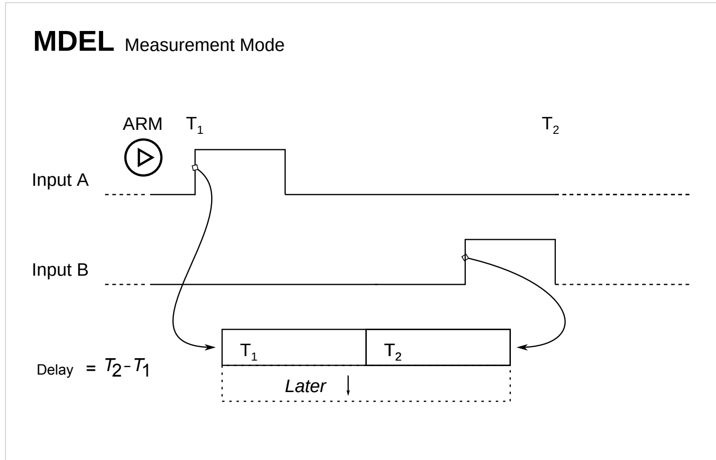
Per ARM block a pre-defined count of measurements can be taken. The default count is 1, for a single measurement per ARM pulse. Setting the block size to zero results in continously taken measurements started at a single ARM pulse.

2 Measurement Modes

2.1 MDEL - Delay (Start/Stop)

Delay is the time difference between the activation of the A and B channel. The delay is positive if the A channel is activated prior to the B channel. The delay is zero if the A and B channel are activated at the same time. The delay is negative if the B channel is activated prior the the A channel.

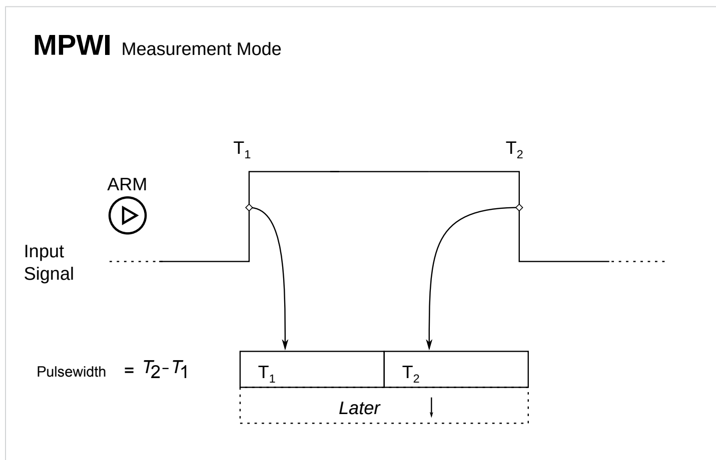
MDEL is activated via class ModeDelay. The tic_delay example demonstrates how to use this mode in an application program.



2.2 MPWI - Pulse Width

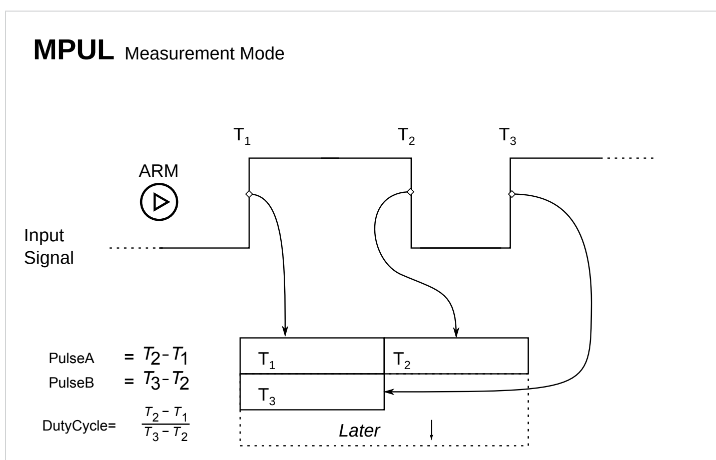
In positive edge mode, pulse width is the distance between the low-to-high and the subsequent high-to-low edge of a pulse. In negative edge mode, pulse width is the distance between the high-to-low and the subsequent low-to-high edge of a pulse. By definition, pulse width is always a non-zero positive value.

MPWI is activated via class ModePulseWidth. The tic_pulsewidth example demonstrates how to use this mode in an application program.



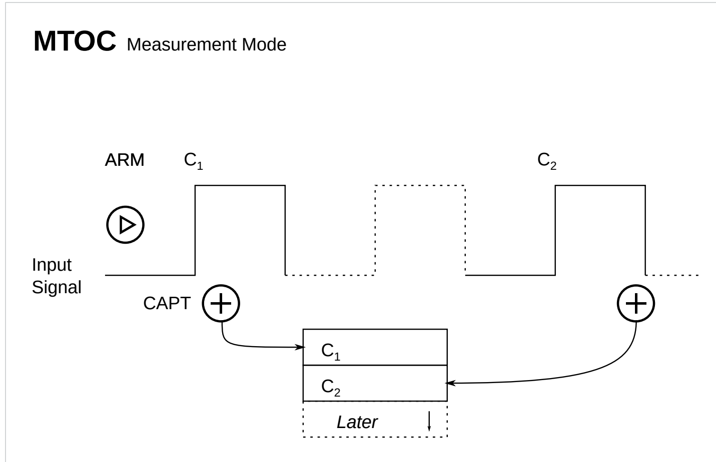
2.3 MPUL - Pulse

This mode measures the active as well as the inactive time of a pulse. The pulse period and the duty cycle are calculated. In positive edge mode, the measurement starts with the low-to-high edge of the input signal. In negative edge mode, the measurement starts with the high-to-low edge of the input signal. The duty cycle is the ratio between the first and the second half of the pulse. By definition, the duty cycle may approach but never reach the value of 0 or 1.



MPUL is activated via class ModePulse. The tic_pulse example demonstrates how to use this mode in an application program.

2.4 MTOC - Totalizing Counter



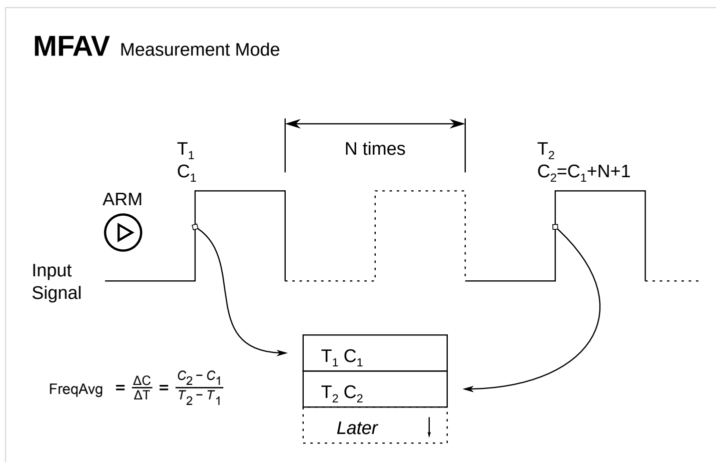
In totalizing counter mode, the Timetag unit continously counts the active edges of the input signal. Only on a CAPT internal pulse, the event is captured. The CAPT signal can be given “on-demand” by software control, external pulse, or on periodic timer intervals. The counter's values along with the respective capture times are available from the analyzer.

In positive edge mode, the low-to-high edges of the input signal are counted. In negative edge mode, the high-to-low edges of the input signal are counted.

MTOC is activated via class ModeTotalCount. The tic_totalcount example demonstrates how to use this mode in an application program.

Note that, while this mode combined with periodic capture is able to provide frequency/period average measurements, a more precise, dedicated mode MFAV is provided (see below).

2.5 MFAV - Frequency Average



For frequency/period average measurements an interval *N* must be selected. An event is captured for every *N*th leading signal edge. The selection of *N* affects measurement time and resolution, see Section 4.

MFAV is activated via class ModeAvg. The tic_freq example demonstrates how to use this mode in an application program.

3 Input Filters

The TIC-8420 provides low-pass (debouncing) filters at each digital input. The filter setting for each input can be configured independently. The table lists the Filter code to set the filter by the application program, the pulse width guaranteed to pass the filter (T_{pass}), the pulse width guaranteed to not pass the filter (T_{glitch}), and the maximum frequency able to pass the filter (f_{max}).

Input Filters

Code	T_{pass}	T_{glitch}	f_{max}
0	2.78 ns	(unfiltered)	180 MHz
31	5.56 ns	2.78 ns	90.0 MHz
33	11.1 ns	5.56 ns	45.0 MHz
35	22.2 ns	11.1 ns	22.5 MHz
37	44.4 ns	22.2 ns	11.3 MHz
8	200 ns	167 ns	2.50 MHz
9	400 ns	333 ns	1.25 MHz
10	800 ns	667 ns	625 kHz
11	1.60 µs	1.33 µs	313 kHz
12	3.20 µs	2.67 µs	156 kHz
13	6.40 µs	5.33 µs	78.1 kHz
14	12.8 µs	10.7 µs	39.1 kHz
15	25.6 µs	21.3 µs	19.5 kHz
16	51.2 µs	42.7 µs	9.77 kHz
17	102 µs	85.3 µs	4.88 kHz
18	205 µs	171 µs	2.44 kHz
19	410 µs	341 µs	1.22 kHz
20	819 µs	683 µs	610 Hz
21	1.64 ms	1.37 ms	305 Hz
22	3.28 ms	2.37 ms	153 Hz
23	6.55 ms	5.46 ms	76.3 Hz
24	13.1 ms	10.9 ms	38.1 Hz

4 Measurement Resolution

The measurement resolution (the number of significant digits of the result) depends on the measurement time only. For example, a pulse of 2.8µs cannot be measured with more than 3 decimal digits resolution by the TIC-8420, whereas a pulse of 2.8ms is measured with 6 digits.

While the resolution is determined by the input signal in most modes, the frequency/period average mode MFAV allows to trade off measurement time against resolution. The is done by selecting a larger *N* to increase resolution (along with measurement time). To speed up measurements, *N* must be decreased at the cost of resolution.

Sign.	Measurement	Sample Freq	Range
2 ½	0.56 µs	1.79 MHz	200
3	2.8 µs	359 kHz	1 k
3 ½	5.6 µs	178 kHz	2 k
4	28 µs	35.9 kHz	10 k
4 ½	56 µs	17.8 kHz	20 k
5	280 µs	3.59 kHz	100 k
5 ½	560 µs	1.78 kHz	200 k
6	2.8 ms	359 Hz	1 M
6 ½	5.6 ms	178 Hz	2 M
7	28 ms	35.9 Hz	10 M
7 ½	56 ms	17.8 Hz	20 M
8	280 ms	3.59 Hz	100 M
8 ½	560 ms	1.78 Hz	200 M
9	2.78 s	0.359 Hz	1 G

5 Programming

The interface to the instrument's hardware is implemented by class TinaPlex. A seperate instance of class TinaPlex is used per timing analyzer connected.

Initialization
The measurement task which is represented by the TinaMode based object must be configured by calling the callTinaConfig() function call. If the measurement is to be armed by software control (i.e. not externally or timer based) callTinaArm() must be called.

Transfer Loop
The transfer loop transfers raw measurement data from the instruments hardware to the analyzer functions implemented in software. The transfer loop must be operated as long as measurements are required. Within the transfer loop callTinaSample() is called.

6 Connecting External Signals

The list explains the input signals to the TIC-8420. GND is the ground-reference for all lines. For input characteristics see Figure 8.

IN-A/B — The input waveform signal. For MDEL measurement the start signal is connected to IN-A, the stop signal to IN-B.

EN-A/B — The input enable signal if external enable is selected. Ignored if external enable is not selected.

ARM-A/B — The arm signal if external arm is selected. Ignored if external arm is not selected.

CAPT-A/B — The external capture signal if external capture is selected. Ignored if external capture is not selected.

TIC-8420 Signal by Pin

Signal	Pin	Connector View	Pin	Signal
3,3V	1		14	GND
IN-A/IO15	2		15	IN-B/IO14
GND	3		16	EN-B/IO13
EN-A/IO12	4		17	GND
ARM-B/IO11	5		18	ARM-A/IO10
GND	6		19	CAPT-B/IO09
CAPT-A/IO08	7		20	GND
IO07	8		21	IO06
GND	9		22	IO05
IO04	10		23	GND
IO03	11		24	IO02
GND	12		25	IO01
IO00	13
